FOREWORD

(U) This Interim Technical Status Report (Contractors Reference No. PWA-3576) was prepared by Pratt & Whitney Aircraft, Division of United Aircraft Corporation, East Hartford, Connecticut, as the second Semiannual Report under United States Air Force Contract F33615-68-C-1208, Project No. 3066, Task No. 306606. This report was submitted by the Contractor on 31 December 1968, and covers the Report period from 1 July 1968 to 31 December 1968.

(U) The findings and conclusions of this report are not deemed as final by the Contractor. They are subject to verification or revision in the Final Report to be published upon the completion of this Contract.

(U) The Air Force Program Monitor is Mr. Jack Richens, APTC, Air Force Aero Propulsion Laboratory, Wright-Patterson Air Force Base, Ohio, 45433.

(U) This report contains no classified information extracted from other classified documents.

(U) Publication of this report does not constitute Air Force approval of the report's findings or conclusions. It is published only for the exchange and stimulation of ideas.

UNCLASSIFIED ABSTRACT

(U) A comprehensive three-year program is in progress to investigate methods of improving the performance of fan-drive turbines. The goals of the program are to develop turbine aerodynamic techniques and design procedures for efficient, high work, low pressure turbines by means of analytical studies and cascade testing, and to demonstrate the effectiveness of the techniques by designing and testing a two stage turbine that meets or exceeds the contract stage work and efficiency goals. The first phase effort defining the preliminary turbine design has been completed and the results have been reported. The second phase consists of a preliminary experimental evaluation which includes establishment of two-dimensional loss levels and three-dimensional flow behavior for both the baseline airfoils and airfoils utilizing boundary layer control devices. The design of the rig hardware and the baseline airfoils which will be evaluated during this second phase are presented in this report.

Distribution of this abstract is unlimited.

SECTION I INTRODUCTION

(U) Aircraft jet engine performance and optimization studies have always included a trade-off between increasing turbine efficiency and reducing the turbine weight. Recently, the bypass turbofan engine has dominated jet engine applications. For this type of engine, the economy generally increases with increasing bypass ratio. However, increased bypass ratios represent increased fan power requirements, which must be met by increased fan-drive turbine power. It is, therefore, necessary to meet these increased turbine loading requirements without penalizing the turbine efficiency.

(U) The fan-drive turbine design is constrained by certain unique requirements. The rotational speed of the turbine must be limited in order that the fan tip Mach number does not exceed the limit for reasonable losses. As the bypass ratio and, therefore, the fan diameter increase, this problem becomes even more critical. Applying conventional aerodynamics, as limiting turbine rotational speeds are approached, increased work can only be realized by increasing the number of stages and/or the turbine diameter. Reduction of the turbine diameter or solidity results in a lighter turbine, but with a sacrifice in efficiency due to losses associated with increased loading. Considerable gains can be realized by an engine if the size and weight reduction can be made with no loss in efficiency. Because of the time required between the evolution of new concepts and engine production, turbine technology must be improved now, so that the desired level of turbofan engine performance can be achieved for aircraft which will be operational in the 1975-1980 time period.

(U) The objective of the work done under this contract is to analyze and test concepts which will increase the low pressure turbine loading and maintain or increase current turbine efficiency levels. The goals of this program are to develop turbine aerodynamic techniques and design procedures for efficient high work, low pressure turbines by means of analytical studies and cascade testing, and to demonstrate the effectiveness of the techniques, by designing and testing a two-stage turbine that meets or exceeds the contract stage work and efficiency goals.

(U) The total program has been planned in four phases over a period of three years. Phase I defined the basic turbine design and an analysis of promising increased loading concepts was completed. The results of the Phase I study is reported in Reference 1 and briefly summarized in Section I of this report. Phases II and III consist of experimental testing to verify and extend the turbine aerodynamic techniques and design procedures for high loading levels. Phase IV will subject the aerodynamic techniques and design procedures to a two-stage rotating rig test.

UNCLASSIFIED

UNCLASSIFIED

(U) Work on this contract during the reporting period proceeded on Phase II. The design and fabrication of both the annular segment and plane cascade airfoils and test rigs has been conducted as scheduled. This report describes this effort. Sufficient test airfoil and rig design details are included for permanent record in order that this hardware can be duplicated in the future, if necessary. Testing has been initiated and the results will be reported in the next Interium Technical Report.

UNCLASSIFIED

CONFIDENTIAL

SECTION II BACKGROUND

(U) The Phase I analysis of this contract has been completed and the results are described in Reference 1. The objective of Phase I was to select a preliminary turbine design that is capable of meeting the performance requirements specified in this Contract (See Table I). The final choice of the preliminary turbine configuration was based on the judgments formed from the analyses generated during Phase I. These analyses included consideration of the flow-path, reaction level, load coefficient level, and variations in work distribution for which velocity triangles were generated.

(U) Preliminary airfoil contours were defined for the velocity triangles for three levels of reaction and three levels of solidity for equal work split stages. Based on the resulting two-dimensional suction surface pressure coefficients and diffusion parameters, the following preliminary airfoils were selected for contour refinement: first vane, first blade and second vane - normal, medium and low solidity; second blade - normal and medium solidity. The selected preliminary airfoil contours were refined further to improve the pressure distribution and increase resistance to flow separation. Modifications of the contours required several iterations on each section to arrive at the desired pressure distribution. Two-dimensional boundary layer calculations were made for the final refined contours. Based on these analyses, the design system has indicated that a number of turbine configurations are capable of meeting the performance requirements of this contract. In particular, the medium reaction, normal solidity turbine promises to meet the required goals. This design was chosen for preliminary evaluation during Phases II and III. For convenience, the pertinent parameters for the chosen design are presented in Tables II and III. As part of Phase II, these baseline airfoils will be tested to determine the nature and extent of the end loss mechanism before selecting, designing, and testing appropriate boundary layer control techniques.

SECTION III

TWO-DIMENSIONAL DESIGN VERIFICATION (TASK IIa)

1. RFP OBJECTIVE

- (U) Provide an experimental verification of the two-dimensional design characteristics.

2. TASK OBJECTIVE

- (U) The purpose of this Task is to conduct plane cascade tests in order to verify the aerodynamic concepts applied to the turbine design during the Phase I program, and to establish the two-dimensional loss levels for the chosen turbine airfoil profiles at design conditions.

- (U) The plane cascade tests will serve two, equally important, purposes. First, the measured profile losses will be compared with those contained in the computer programs to verify the existing design procedures. Second, the total pressure and flow angle profiles at the exit plane will indicate whether or not the surface boundary layer has separated. Each airfoil has been designed so that such two-dimensional separation should not occur, and these tests will constitute a verification of the separation criterion used in the airfoil design.

3. AIRFOIL SECTION AND RIG DESIGN

- (U) A summary of the pertinent airfoil design parameters for the selected baseline turbine as a result of Phase I study are shown in Table IV. The six airfoil sections to be initially tested are the mean section of each airfoil row and the second vane and blade root sections. These profiles will be individually evaluated in order to verify the predicted two-dimensional losses. The cascade packs will consist of straight airfoils having the contours of their respective baseline airfoil design. The airfoil sections are shown in Figures 1 through 6. The dimensions listed in these figures and the coordinates for the airfoils (see the Appendix) show the engine size values. In order to permit a reasonable amount of surface static pressure taps to be installed on the plane cascade airfoils, scaled up airfoils were fabricated for plane cascade testing. Scale factors were 1.840, 2.012, 2.123, 1.921, 2.067, 2.066, for the first vane mean, first blade mean, second vane root, second vane mean, second blade root, second blade mean airfoils, respectively.

- (U) The method of assembly of the cascade test packs is shown in Figure 7 and sketches of each of the individual test packs are shown in Figures 8 thru 13. All packs have airfoils with a span of 7.0 inches. The axial chords are 1.54, 1.14, 1.76, 1.69, 1.35, and 1.19 inches for the first vane mean, first blade mean, second vane root, second vane mean, second blade root and second blade mean airfoils, respectively. The gaps, the stagger angles, and the number of airfoils for each pack are also shown on the assembly sketch, Figure 7. Locations of the exit static taps are also shown for each pack, as well as the airfoil which will have surface static pressure taps, in Figures 8 thru 13. The method of installing of the airfoil surface static pressure taps and their locations for each of the test packs are shown in Figure 14. A total of 25, 20, 15, 16, 17 and 13 surface taps are installed in the first vane mean, first blade mean, second vane root, second vane mean, second blade root and second blade mean airfoils, respectively. The number of surface taps depended on the fabrication limitations imposed by each airfoil chord size.
- (U) The design of the plane cascade rig and the location of the test section on the test stand are shown in Figure 15. Inlet static pressure taps will be installed on the test rig rather than on each test cascade as in the case of the exit static taps. The test section will have a variable inlet and exit flow path in order that all six cascades can be evaluated using basically the same hardware. The variable geometry rig design will permit each cascade to be tested at its respective design incidence angle. Both inlet and exit pressures can be independently controlled, as well as the inlet temperature level, allowing the correct simulation of inlet and exit Mach numbers, as well as the design Reynolds number. The cascade pack exit total pressure and exit flow angle profiles will be measured. Based on these measurements, profile loss coefficients will be determined for the midspan of the instrumented airfoil in the cascade. Local and integrated loss coefficients will be calculated for the test passage width. These midspan profile losses will be compared with the turbine mean line loss as predicted by the design system. The root section profile loss will be compared with the two-dimensional design prediction, verifying its characteristics without the end wall influences.

SECTION IV

BASELINE AIRFOIL EVALUATION (TASK IIb)

1. RFP OBJECTIVE

- (U) Determine the design point performance of the baseline turbine airfoils and the need for corner boundary layer control.

2. TASK OBJECTIVE

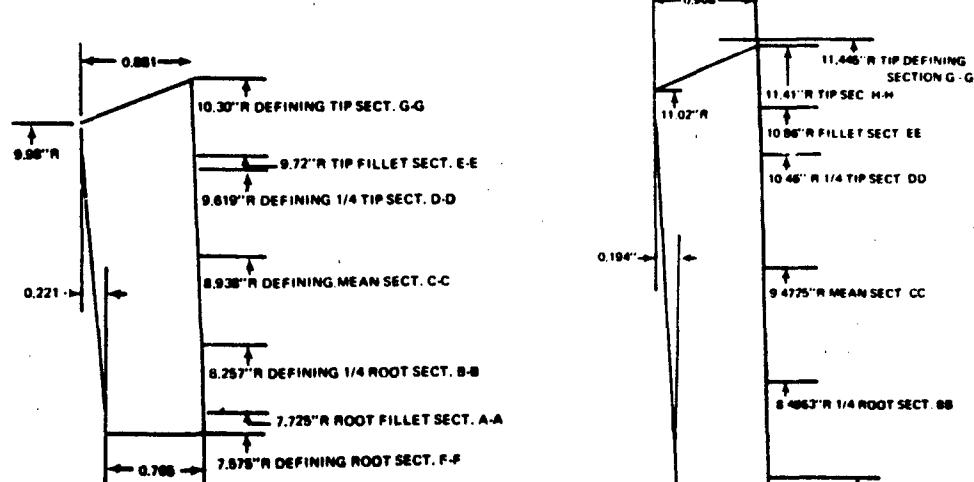

- (U) Each of the baseline airfoil designs as determined by the Phase I portion of this Contract will be evaluated in an annular segment cascade, where the correct three-dimensional flow behavior will be closely reproduced. The purpose of these tests is to evaluate the average losses, so that by subtracting out the plane cascade two-dimensional losses, the net effects of secondary losses can be evaluated for comparison with the present design system secondary loss correlations. Location and severity of losses due to airfoil and/or corner boundary layer separation will be found if they occur. When separation does occur, simple flow visualization techniques will be employed in order to locate the beginning of the region of separation. This information will be required in the following Task where boundary layer control techniques will be applied, since the most effective techniques are those which are applied upstream of the existing point of separation. Furthermore, surface static pressure distributions will be measured on the airfoils in order to verify the aerodynamic concepts used in their design. These static pressure distributions will also assist in determining the location and extent of any regions of separation.

3. ANNULAR SEGMENT CASCADE AIRFOIL AND RIG DESIGN

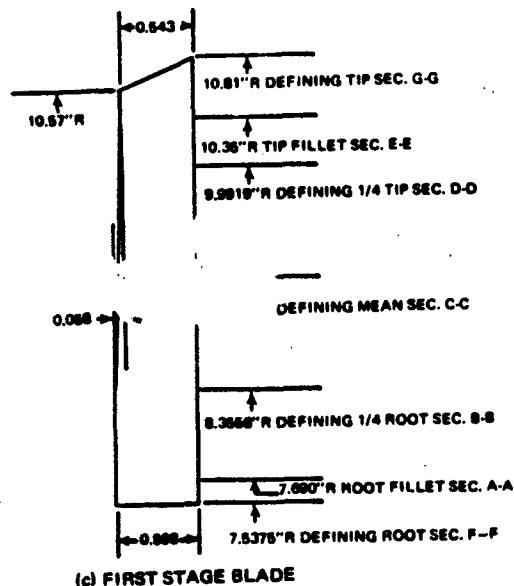

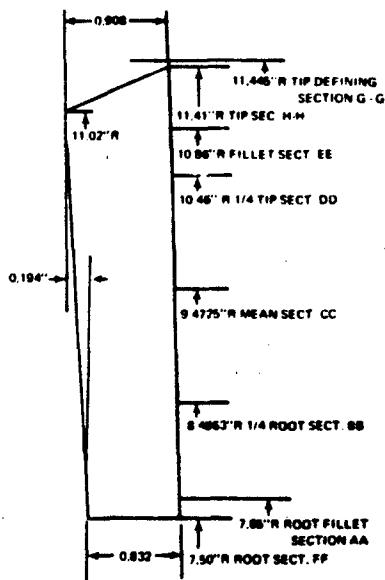

- (U) The elevations of the first stage vane and blade as well as the second stage vane and blade which were determined as a result of the Phase I study are shown in Figure 16. The airfoil sections for the chosen medium reaction, normal solidity design were presented in the Phase I report, Reference 1. The fabrication coordinates for each of the sections indicated in Figure 16 are tabulated, in the Appendix, for the first vane in Tables V through XII, the first blade in Table XIII through XIX, the second vane in Table XX through XXVII, and for the second blade in Tables XXVIII through XXXIV. Additional airfoil information as airfoil angles, gaging distance, airfoil area, axial chord, uncovered turning are also tabulated. These airfoils have been fabricated for evaluation in the annular segment cascade rig.

- (U) The test sections for each of the four airfoils to be evaluated in the annular segment cascade are shown in Figures 17 through 20. The inlet to each cascade consists of a bellmouth transition section followed by a turning vane which aligns the flow with its design angle. The turning vanes are followed by the test airfoils. In each case seven airfoils are used. These test airfoils then are followed by exit wall extensions.
- (U) The turning vane design was generated by applying the turbine streamline analysis program in order to provide proper inlet flow angles over the entire span of the test airfoils. Two long chord guide vanes are used in each cascade unit. The turning vane sector endwalls conform to the turning vane contours providing three uniform flow passages before the test cascades. The central three test airfoils will be between the turning vanes and entirely free of wake disturbances. The elevations, required turning vane exit angle and required test airfoil inlet angles are shown in Figure 21 through 32. The turning vane cross sections are shown in Figures 33 through 64, and the coordinates for these sections are shown in Tables XXXV through LXVI of the Appendix.
- (U) Analyses were also made to determine if potential problems of flow separation exist on the inside end wall extensions downstream of the test airfoils. If such separation occurs, it may trigger separation on the test airfoils and thus produce false indications of airfoil performance. The results of the analyses, fortunately, indicate that the end wall extension is sufficiently long to maintain a small enough pressure gradient to prevent separation.
- (U) Sufficient instrumentation is installed on the rig, on the flow path walls and airfoil surfaces to determine the loss coefficients and exit flow deviations for these cascades. Surface static pressure tap locations were installed on all four of the baseline airfoils as shown in Figure 65. The method of installing the taps is also indicated in this Figure. A total of 30 static taps were installed on each test channel. Static taps will be located at the midspan section as well as near the root and tip sections to obtain data in the end wall regions.
- (U) A single cone probe as shown in Figure 66 was chosen for the exit plane total and static pressure and angle traverse requirements. This probe will be positioned parallel to the midspan streamline. The resulting pitch angles with respect to the cascade end walls were analytically estimated. The probe was also calibrated to determine total and static pressure errors due to pitch angle over the test Mach number range. Based on these probe calibrations, corrections for pitch angle were added to the data reduction program.

- (U) A traversing probe was also installed just upstream of the test airfoils in order to measure the losses due to the turning vane, and to measure the actual inlet flow angle seen by the test airfoils. Turning vane losses will be accounted for in the data reduction program used to calculate the test airfoil performance.
- (U) The completed annular segment cascade test sections have been received from fabricators. One of these is shown in Figure 67 to 72. The first vane cascade was installed in the test rig (Figures 73 and 74) and checkout runs have been completed.

SECTION V

PRELIMINARY DESIGN MANUAL PREPARATION (TASK IIe)

1. RFP OBJECTIVE

- (U) Prepare the preliminary draft of the Turbine Design Procedure Manual.

2. TASK OBJECTIVE

- (U) The purpose of this task is to prepare and deliver a Turbine Design Procedure Manual. This manual will contain, for each computer program used to design the contract turbine, the following information: a flow diagram; a listing for all input and output items and their definitions; a list of definitions for each term used in the computer code; a writeup of the pertinent engineering equations; listing of the computer code in Fortran IV; a copy of the computer program deck in Fortran IV; any necessary test cases for deck checkout.

3. STATUS

- (U) Work is in progress on the following computer programs:
 - (a) Turbine Mean Line Design Program
 - (b) Turbine Stage Off Design Program
 - (c) Turbine Streamline Analysis Program
 - (d) Airfoil Pressure Distribution Program
 - (e) Airfoil Boundary Layer Program
 - (f) Turbine Airfoil Design and Section Properties Program
 - (g) Airfoil Curved Line Fairing Program
 - (h) Airfoil Straight Line Fairing Program

13. ABSTRACT			
(U) A comprehensive three-year program is in progress to investigate methods of improving the performance of fan-drive turbines. The goals of the program are to develop turbine aerodynamic techniques and design procedures for efficient, high work, low pressure turbines by means of analytical studies and cascade testing, and to demonstrate the effectiveness of the techniques by designing and testing a two stage turbine that meets or exceeds the contract stage work and efficiency goals. The first phase effort defining the preliminary turbine design has been completed and the results have been reported. The second phase consists of a preliminary experimental evaluation which includes establishment of two-dimensional loss levels and three-dimensional flow behavior for both the baseline airfoils and airfoils utilizing boundary layer control devices. The design of the rig hardware and the baseline airfoils which will be evaluated during this second phase are presented in this report.			
Distribution of this abstract is unlimited.
